## Solubility of the gases

- The principal atmospheric gases that go into solution are oxygen, nitrogen, carbon dioxide.
- All water exposed to atmosphere will have these gases in solution.
- Other gases in solution are ammonia $\left(\mathrm{NH}_{3}\right)$, hydrogen sulphide $\left(\mathrm{H}_{2} \mathrm{~S}\right)$, and methane $\left(\mathrm{CH}_{4}\right)$, which are associated with microbial activity.
- The amount of particular gas dissolved in water depends upon:
o Its solubility in water
o Its partial pressure at the air/water interface
o Temperature of water
o Level of salts in the water
If water contains as much as specific gas that it can hold in the presence of an abundant supply, then the water is said to be saturated.
o E.g., saturation concentration of oxygen in water at $20^{\circ} \mathrm{C}$ is $9.3 \mathrm{mg} / \mathrm{L}$.
o If oxygen content is $7.5 \mathrm{mg} / \mathrm{L}$ at $20^{\circ} \mathrm{C}$, it is $80 \%$ saturated.
o When oxygen content exceeds $100 \%$, it is said to be supersaturated.
Supersaturation occurs because of:
o High photosynthetic activity (in summer)
o When high temperature water is discharged to river, the rapid rise in water temperature causes $\mathrm{O}_{2}$ supersaturation.

The solubility of gases in water is related to the partial pressure of the gas in the atmosphere above the water (by Henry's law).

$$
\mathrm{P}_{\mathrm{g}}=\mathrm{K}_{\mathrm{h}} \cdot \mathrm{X}_{\mathrm{g}}
$$

where, $\mathrm{P}_{\mathrm{g}}=$ Partial pressure of gas, atm.
$\mathrm{K}_{\mathrm{h}}=$ Henry's law constant, atm/mole
$\mathrm{X}_{\mathrm{g}}=$ Equilibrium mole fraction of dissolved gas
$\mathrm{X}_{\mathrm{g}}=$ Mole of gas $\left(\mathrm{n}_{\mathrm{g}}\right) /\left\{\right.$ mole of gas $\left(\mathrm{n}_{\mathrm{g}}\right)+$ mole of water $\left.\left(\mathrm{n}_{\mathrm{w}}\right)\right\}$

For example: As air contains nearly $21 \% \mathrm{O}_{2}$, the partial pressure of $\mathrm{O}_{2} \approx 0.21 \mathrm{~atm}$
Henry's law constant for common gases soluble in water, $K_{h} \times 10^{-4} \mathrm{~atm} / \mathrm{mole}$

| Temperature | $\mathrm{N}_{2}$ | $\mathrm{O}_{2}$ | $\mathrm{CO}_{2}$ | $\mathrm{H}_{2} \mathrm{~S}$ | $\mathrm{CH}_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 5.29 | 2.55 | 0.073 | 0.027 | 2.24 |
| 10 | 6.68 | 3.27 | 0.104 | 0.037 | 2.97 |
| 20 | 8.04 | 4.01 | 0.142 | 0.048 | 3.76 |
| 30 | 9.24 | 4.75 | 0.186 | 0.061 | 4.49 |

Example: Determine saturation concentration of $\mathrm{O}_{2}$ in water at $10^{\circ} \mathrm{C}$ at 1 atm.

## Solution:

$\mathrm{O}_{2}$ is $21 \%$ in air (v/v), hence, $\mathrm{Pg}=0.21 \times 1 \mathrm{~atm}=0.21 \mathrm{~atm}$
Henry's law constant $\mathrm{K}_{\mathrm{h}}=3.27 \times 10^{4} \mathrm{~atm} / \mathrm{mole}$ at $10^{\circ} \mathrm{C}$.
Now $\mathrm{P}_{\mathrm{g}}=\mathrm{K}_{\mathrm{h}} . \mathrm{X}_{\mathrm{g}}$
Therefore $\mathrm{X}_{\mathrm{g}}=\mathrm{P}_{\mathrm{g}} / \mathrm{K}_{\mathrm{h}}$
$\mathrm{X}_{\mathrm{g}}=0.21 /\left(3.27 \times 10^{4}\right)=6.42 \times 10^{-6}$ (equilibrium mole fraction)
Since, 1 mole of water is 18 g , hence mole/L for water $\left(\mathrm{n}_{\mathrm{w}}\right)=1000 / 18=55.6 \mathrm{~mole} / \mathrm{L}$
Now $=\mathrm{X}_{\mathrm{g}}=\mathrm{n}_{\mathrm{g}} /\left(\mathrm{n}_{\mathrm{g}}+\mathrm{n}_{\mathrm{w}}\right)$
Solving for $\mathrm{n}_{\mathrm{g}}, \quad \mathrm{n}_{\mathrm{g}}=3.57 \times 10^{-4} \mathrm{~mole} / \mathrm{L}$
Saturation concentration of $\mathrm{O}_{2}$ :
$\mathrm{Cs}=\mathrm{n}_{\mathrm{g}} . \mathrm{M}$
Where, $\mathrm{M}=$ molecular wt. of oxygen
$\mathrm{Cs}=3.57 \times 10^{-4} \mathrm{~mole} / \mathrm{L} \times 32 \mathrm{~g} / \mathrm{mole} \times 10^{3} \mathrm{mg} / \mathrm{g}=11.4 \mathrm{mg} / \mathrm{L}$
Example: Determine saturation concentration of $\mathrm{CO}_{2}$ in water at $20^{\circ} \mathrm{C}$ at 1 atm. Air contains $0.033 \% \mathrm{CO}_{2}(\mathrm{~V} / \mathrm{V}), \mathrm{Kh}=0.142 \times 10^{4} \mathrm{~atm} / \mathrm{mole}$.

## Solution:

$\mathrm{x}_{\mathrm{g}}=0.00033 /\left(0.142 \times 10^{4}\right)=0.233 \times 10^{-6}$
$\mathrm{X}_{\mathrm{g}}=\mathrm{n}_{\mathrm{g}} /\left(\mathrm{n}_{\mathrm{g}}+\mathrm{n}_{\mathrm{w}}\right)$
Therefore, for $\mathrm{n}_{\mathrm{w}}=55.6 ; \mathrm{n}_{\mathrm{g}}=0.13 \times 10^{-4} \mathrm{~mole} / \mathrm{L}$
Saturation concentration
Cs $=0.13 \times 10^{-4} \times(12+32) \times 10^{3}=0.57 \mathrm{mg} / \mathrm{L}$ at $20^{\circ} \mathrm{C}$ and 1 atm .
Example: Determine solubility of $\mathrm{CH}_{4}$ in UASB reactor operated at $30{ }^{\circ} \mathrm{C}$ at 1 atm The partial pressure of methane inside the reactor would be $0.8 \mathrm{~atm} . \mathrm{K}_{\mathrm{h}}=4.49 \mathrm{x}$ $10^{4} \mathrm{~atm} / \mathrm{mole}$.

## Solution

$\mathrm{P}_{\mathrm{g}}=\mathrm{K}_{\mathrm{h}} . \mathrm{X}_{\mathrm{g}}$
Therefore $\mathrm{X}_{\mathrm{g}}=\mathrm{P}_{\mathrm{g}} / \mathrm{K}_{\mathrm{h}}$
$\mathrm{X}_{\mathrm{g}}=0.8 /\left(4.49 \times 10^{4}\right)=1.78 \times 10^{-5}$ (equilibrium mole fraction)
Since, 1 mole of water is 18 g , hence mole/L for water $\left(\mathrm{n}_{\mathrm{w}}\right)=1000 / 18=55.6$ mole/L
Now $=X_{g}=n_{g} /\left(n_{g}+n_{w}\right)$
Solving for $\mathrm{n}_{\mathrm{g}}, \quad \mathrm{n}_{\mathrm{g}}=9.906 \times 10^{-4} \mathrm{~mole} / \mathrm{L}$
Saturation concentration:
$\mathrm{Cs}=\mathrm{n}_{\mathrm{g}} . \mathrm{M}$
Where, $\mathrm{M}=$ molecular wt. of $\mathrm{CH}_{4}$
Cs $=9.906 \times 10^{-4} \mathrm{~mole} / \mathrm{L} \times 16 \mathrm{~g} / \mathrm{mole} \times 10^{3} \mathrm{mg} / \mathrm{g}=15.85 \mathrm{mg}$ of $\mathrm{CH}_{4} / \mathrm{L}$

## Aeration and Mass transfer

Aeration is used in wastewater treatment for:

- Transfering $\mathrm{O}_{2}$ in biological treatment processes.
- For stripping solvents from wastewater.
- Removing volatile gases such as $\mathrm{H}_{2} \mathrm{~S}, \mathrm{NH}_{3}$

Aeration is gas-liquid mass transfer process in which interphase diffusion occurs.

Other gas transfer - chlorine gas - for disinfection.

## Description of gas transfer

- $\mathrm{O}_{2}$ transfer in wastewater treatment is most common.
- For transfering sufficient $\mathrm{O}_{2}$, additional surface than normal water surface should be brought in contact with air or $\mathrm{O}_{2}$
- Either air or $\mathrm{O}_{2}$ is introduced in liquid
- Or water droplets are exposed to air.

## Commonly used aeration devices

Type Description Uses of application

## Diffuse air

Porous
(fine bubble)
Porous
(medium bubble)
Non porous
(coarse bubble)
Jet

## Surface aerator

Low speed turbine aerator

Sparger turbine Low- speed turbine and compressed injection system
Ceramic, vitreous, porous plates with resin, domes, All types of ASP tubes

Perforated membrane or plastic tubes

Bubbles generated from orifices, nozzles etc.

Compresses air injected into mixed liquor

Large dia. turbine used to expose liquid droplets to atmosphere.

Conventional ASP. Aerated lagoon.

High -speed floating aerator

Rotar -brush aerator

Small-dia. propeller used to expose liquid droplets to atmosphere

Blades mounted on central shaft are rotated through liguid.
$\mathrm{O}_{2}$ is introduced by splashing action of blades \& liquid droplet formation

Cascade
Wastewater flows over cascade in sheet flow
Post aeration

Figure 13.1 Sparger turbine aerator

Analysis of gas transfer: The two film theory: (This is better than other theories with $95 \%$ cases accurate results).

$\mathrm{P} \& \mathrm{Pi}=$ Partial pressure of solute in bulk gas and at the interface, atm
$\mathrm{C}, \mathrm{Ci}=$ solute concentration in bulk water and at interfaces, $\mathrm{mg} / \mathrm{L}$
Two flims

- One liquid and one gas
- These two films provide resistance to the passage of gas molecules from gas phase to liquid phase.
- Slightly soluble gas encounters primary resistance to transfer from liquid film.
- Very soluble gases encounter primary resistance from gaseous film
- Intermidiate solubility encounters significant resistance from both films.

## Addition of gases

The rate of gas transfer is propotional to difference between existing concentration and equilibrium concentration of the gas in solution. (Saturation conc. \& existing conc.)

$$
r_{m}=k_{g} A\left(C_{s}-C\right)
$$

where,
$\mathrm{r}_{\mathrm{m}}=$ rate of mass transfer,
$\mathrm{k}_{\mathrm{g}}=$ coefficient of diffusion for gas,
A = area through which gas is diffusing
$\mathrm{C}_{\mathrm{s}}=$ saturation concentration of gas in solution
$\mathrm{C}=$ concentration of gas in solution
Under condition of mass transfer in field $r_{m}=\forall . d c / d t \& r_{c}=\frac{r_{m}}{\forall}$
$r_{c}=\frac{d c}{d t}=K_{g} \frac{A}{V}\left(C_{s}-C\right)$
The term $K_{g}\left(\frac{A}{V}\right)$ is replaced by ' $\mathbf{K}_{\mathbf{L}} \mathbf{a}$ ' a proportionality factor related to existing exposer conditions.
$r_{c}=\frac{d c}{d t}=K_{L} a\left(C_{s}-C\right)$
Where: $r_{c}=$ rate of change in concentration, $\mathrm{mg} / \mathrm{L} . \mathrm{s}$

$$
\mathrm{K}_{\mathrm{L}} \mathrm{a}=\text { overall mass transfer coefficient, } \mathrm{s}^{-1}
$$

Integrating between the limits $\mathrm{C}=\mathrm{C}_{0}$ at $\mathrm{t}=0$ and $\mathrm{C}=\mathrm{Ct}$ at $\mathrm{t}=\mathrm{t}$

$$
\begin{aligned}
\int_{c}^{c t} \frac{d c}{C_{s}-C} & =K_{L} a \int_{0}^{t} d t \\
\frac{C_{s}-C_{t}}{C_{s}-C_{0}} & =e^{-\left(K_{L} a\right) \cdot t}
\end{aligned}
$$

$(\mathrm{Cs}-\mathrm{Ct})$ and $(\mathrm{Cs}-\mathrm{Co})$ represents the final and initial oxygen saturation deficits.

## For Removal of gases

Where a supersaturated solution is to be degassed then equation is modified as

$$
\frac{C_{t}-C_{s}}{C_{o}-C_{S}}=e^{-\left(K_{L} a\right) \cdot t}
$$

## Evaluation of $\mathbf{O}_{\mathbf{2}}$ - Transfer Coefficient

## $\mathrm{O}_{2}$ tranfer in clean water:

- Remove DO from known volume of water by adding sodium sulphite.
- Carry out reoxygenation to near the saturation level.
- During reaeration monitor DO concentration at several representative poins of the tank.
- The data obtained is analyzed by above equation to estimate $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ and equilibrium concentration $\mathrm{C}_{\mathrm{x}}{ }^{*} . \mathrm{C}_{\mathrm{x}} *$ is obtained when aeration period approaches infinity. The term Cs is substituated by Cx.
- A nonlinear regression is employed to fit the equation to the DO profile measured at each determination point.
- In this way, estimate $\mathrm{K}_{\mathrm{L}} \mathrm{a} \& \mathrm{Cx} *$ for each point.
- Adjust if it standard conditions and avg. it to get $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ (ASTM procedure).

## Oxygen transfer in wastewater:

- In ASP, the $\mathrm{K}_{\mathrm{L}}$ a can be determined by considering the uptake of $\mathrm{O}_{2}$ by microorganisms.
- Typical $\mathrm{O}_{2}$ concentration is 1 to $3 \mathrm{mg} / \mathrm{l}$ in aeration tank, and it is used by microorganisms rapidly

$$
\frac{d c}{d t}=K_{L} a\left(C_{s}-C\right)-r_{m}
$$

Where, $\mathrm{r}_{\mathrm{m}}=$ rate of $\mathrm{O}_{2}$ used by the microorganism. (typical value 2 to $7 \mathrm{~g} / \mathrm{d} . \mathrm{g}$ MLVSS)
If DO level is constant $\mathrm{r}_{\mathrm{m}}=\mathrm{K}_{\mathrm{L}} \mathrm{a}(\mathrm{Cs}-\mathrm{C})$
Value of $r_{m}$ can be determined in laboratory (by Wargburg apparatus or respirometer).
Then $\mathrm{K}_{\mathrm{L}} \mathrm{a}=\frac{r_{m}}{C_{s}-C}$

## Factors Affecting oxygen Transfer

## 1) Effect of temperature

The effect of temperature is similar as that in BOD rate coefficient. Using van't Hoff-Arrhenius relationship

$$
K_{L} a_{(T)}=K_{L a\left(20^{\circ} C\right)} \theta^{(T-20)}
$$

Where, $\mathrm{K}_{\mathrm{L}} \mathrm{a}_{(\mathrm{T})}=$ Oxygen mass-transfer coefficient at temp $\mathrm{T}, \mathrm{S}^{-1 .}$
$\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\left(20^{\circ} \mathrm{C}\right)}=$ Oxygen mass transfer coefficient at $20^{\circ}, \mathrm{S}^{-1}$
$\theta=$ varies with test conditions. (Range 1.015-1.040).
$\theta=1.024-$ Typical value used for diffused and mechanical aeration device.

## 2) Effect of mixing intensity and Tank Geometry

- Difficult to estimate on theoritical basis.
- Aeration devices are selected based on efficiency of $\mathrm{O}_{2}$ transfer.
- Efficiency is strongly relatedd to $\mathrm{K}_{\mathrm{L}}$ a value associated with given aeration unit.
- In most cases aeration devices are rated with range of operating conditions using tap water i.e. (low TDS water).
- Hence correction factor $(\alpha)$ is used to estimate $\mathrm{K}_{\mathrm{L}}$ a for actual system

$$
\alpha=\frac{K_{L} a(\text { wastewater })}{K_{L} a(\text { tap water })}
$$

$\alpha$ - Value varies with type of aeration device, basin geomtry, degree of mixing, \& wastewater characteristics.
$\alpha=0.3$ to 1.2 in general range
$=0.4$ to 0.8 for diffused aeration
$=0.6$ to 1.2 for mechanical aeration
3) Effect of wastewater characteristics: Due to difference in saturation concentration

- A correction factor ' $\beta$ ' is used correct the test result for differences in $\mathrm{O}_{2}$ solubility due to constituent such as salts, particulate and surface active substances.

$$
\beta=\frac{C_{s}(\text { wastewater })}{C_{s}(\text { tap water })}
$$

$\beta=0.7$ to 0.98 - value 0.95 is commonly used for wastewater.

## Application of correction factors

The correction factors are applied to predict field oxygen transfer rates besed on the measurements made in experimental test facilities (for mechanical surface aerator).

$$
O T R_{f}=\operatorname{SOTR} \frac{\left(\beta C_{S}-C_{W}\right)}{C_{S 20}} \theta^{(T-20)}(\alpha)
$$

Where, $\mathrm{OTR}_{\mathrm{f}}=$ actual $\mathrm{O}_{2}$ transfer rate under test conditions, $\mathrm{kg} \mathrm{O}_{2} / \mathrm{k}$.W.h
SOTR $=$ standardized $\mathrm{O}_{2}$-transfer rate under test conditions, at $20^{\circ} \mathrm{C}$ and zero D0, kg $\mathrm{O}_{2} /$ k.W.h
$\mathrm{Cs}=\mathrm{O}_{2}$ saturation concentration for tap water at field -operating conditions, mg/L
$\mathrm{Cw}=$ Operating oxygen concentration in wastewater, $\mathrm{mg} / \mathrm{L}$
$\mathrm{C}_{\mathrm{S} 20}=\mathrm{O}_{2}$ saturation concentration for tap water at $20^{\circ} \mathrm{C}, \mathrm{mg} / \mathrm{L}$
For diffused air aeration system, the Cs values must be corrected to account for higher than atmospheric $\mathrm{O}_{2}$ saturation concentration achieved due to application of air at the reactor bottom.

The Cs is taken as average DO attained at infinit time.
(Refer.Ex 6-11 Metcalf page-285 for problem on determination of $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ )

Or, $N=N_{0} \frac{\left(\beta C_{s}-C_{w}\right)}{C_{s 20}} \alpha \cdot \theta^{(T-20)} \quad$ (As per Eckenfelder)
Where, No $=$ SORT $=K_{L}$ a. V.Cs
Example: A step aeration activated sludge process is being designed using the diffused- aeration system. The design criteria for the period of critical oxygen demand in the aeration basin are as follows.

BOD loading $=1.268 \mathrm{~kg} \mathrm{BOD} / \mathrm{m}^{3} . \mathrm{d}$
Oxygen transfer requirement $=1 \mathrm{~kg}$ of $\mathrm{O}_{2} / \mathrm{kg}$ of BOD applied.
Temp. of mixed liquor $=14^{\circ} \mathrm{C}$
Min. allowable DO = $2.0 \mathrm{mg} / \mathrm{l}$
$\alpha=0.70 ; \beta=0.90$

Oxygen transfer coefficient $\left(\mathrm{K}_{\mathrm{L}} \mathrm{a}\right)_{20}=12 \mathrm{hr}^{-1}$
$\mathrm{O}_{2}$ transfer efficiency $=6.0 \%$
Pressure at mid depth of diffusers $=810 \mathrm{~mm}$ of Hg
Compare the rate of oxygen transfer dc/dt to the rate of $\mathrm{O}_{2}$ utilization ' $r$ ' and calculate the volume of standard air required per kg of BOD applied.

Consider Cs at 810 mm Hg and $14^{\circ} \mathrm{C}$ as $=11.1 \mathrm{mg} / \mathrm{L}$

## Solution:

Correcting ( $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ ) 20 for $14{ }^{\circ} \mathrm{C}$
$\mathrm{K}_{\mathrm{L}}$ a at $14^{\circ} \mathrm{C}=(\mathrm{KLa})_{20}(1.024)^{14-20}=10.4 \mathrm{hr}^{-1}$
Now dc/dt $=\alpha \mathrm{K}_{\mathrm{L}} \mathrm{a}\left(\beta \mathrm{C}_{\mathrm{S}}-\mathrm{C}_{\mathrm{t}}\right)$

$$
=0.70 \times 10.4(0.90 \times 11.1-2.0)=58.17 \mathrm{mg} / \mathrm{L} . \mathrm{hr}
$$

Considering 1 kg of oxygen utilized per kg of BOD applied, then the rate of dissolved oxygen utilization is (This will change if actual cell production and BOD ultimate is considered)

$$
\mathrm{r}=1.268 \frac{\mathrm{KgBOD}}{\mathrm{~m}^{3} \cdot \mathrm{~d}}=1.268 \frac{\mathrm{mgBOD}}{\mathrm{~L}} \times \frac{1}{24} \times 10^{3}=52.8 \frac{\mathrm{mg}}{\mathrm{~L} . \mathrm{hr}}
$$

The $\mathrm{O}_{2}$ transfer rate of the aeration system is adequate, since higher than utilization rate (Since $\mathrm{dc} / \mathrm{dt}$ exceeds ' $r$ '). This oxygen resource limits the loading rate on aerobic reactor.

The efficiency of oxygen transfer is proposonal to the rate of oxygen transfer.

$$
\begin{aligned}
\mathrm{E}_{\text {actual }} & =6.0 \frac{\alpha . K_{L a .}(\beta C s-C t)}{\left(K_{l a}\right)_{20}(C s)_{20}} \quad\left(\text { For }\left(\mathrm{K}_{\mathrm{L}} \mathrm{a}\right)_{20} \text { efficiency is } 6 \%\right. \text { hence for actual?) } \\
& =\frac{6.0 \times 0.7 \times 10.4(0.9 \times 11.1-2.0)}{12.0 \times 9.8} \\
& =2.96 \%
\end{aligned}
$$

The volume of standard air required at an actual oxygen transfer efficiency of 2.96\% per kg of BOD load, (considering $1 \mathrm{~kg} \mathrm{O}_{2}$ utilised per kg of BOD applied ) is
$\frac{1.0 \mathrm{~kg} \text { of } \mathrm{O}_{2}}{0.0296 \times 0.279 \mathrm{~kg} \text { of } \mathrm{O}_{2} / \mathrm{m}^{3}}=121 \mathrm{~m}^{3} / \mathrm{kg}$ of BOD applied

Considering one cubic meter of air at temperature and pressure of $14^{\circ} \mathrm{C}$ and 760 mm contains $0.279 \mathrm{~kg} \mathrm{O}_{2} / \mathrm{m}^{3}$.

## Example:

If the saturation concentration of $\mathrm{O}_{2}$ in water is $9.2 \mathrm{mg} / \mathrm{L}$ and initial concentration Co is $2.1 \mathrm{mg} / \mathrm{L}$, determine the time it takes for the concentration Ct to become $7.5 \mathrm{mg} / \mathrm{L}$ if $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ is $0.25 / \mathrm{day}$. What is the time required for Ct to be $5.0,6.0,7.0,8.0$ and $9.0 \mathrm{mg} / \mathrm{L}$ ?

Solution:
$\log \frac{C_{s}-C_{0}}{C_{s}-C_{t}}=\left(K_{L} a\right) . t$
$t=\frac{1}{K_{L} a} \log _{e} \frac{(C s-C o)}{(C s-C t)}$
For $\mathrm{Ct}=7.5 \mathrm{mg} / \mathrm{L}, \mathrm{t}=\frac{1}{0.25} \log _{e} \frac{(9.2-2.1)}{(9.2-7.5)}=5.7$ days
Similarly

| Ct | Time t(days) | If left molecular diffusion alone, several <br> days are required for reoxygenation to <br> occur. However, in most rivers, there is <br> some turbulent diffusion in addition to |
| :--- | :--- | :--- |
| 6 | 2.1 | molecular diffusion; therefore, in reality |
| 7 | 4.2 | the reaeration time is significantly less. |
| 7.5 | 5.7 |  |
| 8 | 7.1 |  |
| 8.5 | 9.3 |  |
| 9 | 14.3 |  |

Volatilization and Gas stripping (of volatile organic compounds)
VOC - such as tricholoroethylene (TCE); 1,2-dibromo-3-chloropane (DBCP), etc.

## Emission of VOCs

The principal mechanisms governing the release of VOCs in wastewater collection and treatment facilities are (i) volatilization and (2) gas stripping.

## Volatilization

- Release of VOCs from wastewater surface to the atmosphere.
- These compounds are released because they partition between the gas and water phase until equilibrium is reached.
- Mass transfer between two phases is function of concentration in each phase relative to equilibrium concentration.
o Thus, transfer is greatest when the concentration in one of the phases is far from equilibrium.
o Since, VOC in atmosphere is extremely low, transfer of VOC usually occurs from wastewater to atmosphere.

## Gas Stripping:

- When air is introduced in water, stripping of VOCs occurs.
- When gas is introduced into wastewater, VOCs are transferred from the wastewater to the gas by the principal explained above.
- In wastewater treatment, air stripping occurs in aerated grit chambers, aerated biological treatment and aerated transfer channels.

## Mass-Transfer rates of VOCs

Mass transfer can be modeled using following equation

$$
r_{\mathrm{VOC}}=-\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{VOC}}(\mathrm{C}-\mathrm{Cs})
$$

where, $\mathrm{r}_{\text {VOC }}=$ rate of VOC transfer, $\mu \mathrm{g} / \mathrm{m}^{3} . \mathrm{h}$
$K_{L} a_{\text {VOC }}=$ Overall VOC mass transfer coefficient, $h^{-1}$
$\mathrm{C}=$ Concentration of VOC in liquid, $\mu \mathrm{g} / \mathrm{m}^{3}$
$\mathrm{Cs}=$ Saturation concentration of VOC in liquid, $\mu \mathrm{g} / \mathrm{m}^{3}$
The mass transfer coefficient of VOC, is proportional to the mass transfer coefficient for oxygen

$$
\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{voc}}=\psi\left(\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{O} 2}\right)
$$

$\psi=$ Coefficient of proportionality and $\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{O} 2}$ is overall oxygen mass transfer coefficient.
The range of values for coefficient of proportionality $\psi$ is 0.55 to 0.65 and it is necessarily same for clear water as for wastewater.

The saturation concentration of VOC in wastewater is function of partial pressure of VOC in atmosphere in contact with wastewater. This is given by Henry's Law as
$\mathrm{Cg} / \mathrm{Cs}=\mathrm{Hc}$
Where, $\mathrm{Cg}=$ concentration of VOC in gas phase $\left(\mu \mathrm{g} / \mathrm{m}^{3}\right)$
$\mathrm{Cs}=$ Saturation concentration of VOC in liquid phase $\left(\mu \mathrm{g} / \mathrm{m}^{3}\right)$
Hc = Henry's law constant, unitless (values available in books for different gases)
Following relation can be used to convert unitless constant values to Henry’s law
$\mathrm{Hc}=\mathrm{K}_{\mathrm{H}} /$ R. T
$\mathrm{K}_{\mathrm{H}}=$ Henry's law constant, atm/g-mole
$\mathrm{R}=$ Universal gas constant, $0.000082057 \mathrm{~atm} / \mathrm{g}$-mole. ${ }^{\circ} \mathrm{K}$
$\mathrm{T}=$ Temperature, ${ }^{\circ} \mathrm{K}=273+{ }^{\circ} \mathrm{C}$

## Mass Transfer of VOCs from Surface Aeration

Material balance for the stripping of VOC from CSTR is as follows
Accumulation $=$ inflow - outflow + generation
$\mathrm{V}(\mathrm{dc} / \mathrm{dt})=\mathrm{Q}_{\mathrm{L}} \cdot \mathrm{C}_{\mathrm{L}, \mathrm{i}}-\mathrm{Q}_{\mathrm{L}} \cdot \mathrm{C}_{\mathrm{L}, \mathrm{e}}+\mathrm{r}_{\mathrm{Voc}} \cdot \mathrm{V}$
Where, $\mathrm{V}=$ Volume of completely mixed reactor, $\mathrm{m}^{3}$
$\mathrm{dc} / \mathrm{dt}=$ rate of change of VOC concentration in reactor, $\mu \mathrm{g} / \mathrm{m}^{3} . \mathrm{h}$
$\mathrm{Q}_{\mathrm{L}}=$ Liquid flow rate ( $\mathrm{m}^{3} / \mathrm{s}$ )
$\mathrm{C}_{\mathrm{L}, \mathrm{i}}=$ Concentration of VOC in influent, $\mu \mathrm{g} / \mathrm{m}^{3}$
$\mathrm{C}_{\mathrm{L}, \mathrm{e}}=$ Concentration of VOC in effluent, $\mu \mathrm{g} / \mathrm{m}^{3}$
$r_{\text {VOC }}=$ rate of VOC mass transfer, $\mu \mathrm{g} / \mathrm{m}^{3} . \mathrm{h}$
Now,
$r_{\text {VOC }}=-K_{L} a_{\text {VOC }}\left(C_{L, e}-C s\right)$
Hence,
$\mathrm{dc} / \mathrm{dt}=(1 / \theta)\left(\mathrm{C}_{\mathrm{L}, \mathrm{i}}-\mathrm{C}_{\mathrm{L}, \mathrm{e}}\right)-\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{VOC}}\left(\mathrm{C}_{\mathrm{L}, \mathrm{e}}-\mathrm{Cs}\right)$
Where $\theta=\mathrm{V} / \mathrm{Q}$
Assuming steady state condition, hence $\mathrm{dc} / \mathrm{dt}=$ zero and Cs is assumed to be zero
$0=\left(C_{L, i}-C_{L, e}\right)-K_{L} a_{\text {voc }}\left(C_{L, e}-C s\right) \theta$
$=\mathrm{C}_{\mathrm{L}, \mathrm{i}}-\mathrm{C}_{\mathrm{L}, \mathrm{e}}\left[1+\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\text {voc }} . \theta\right]$
Then amount of VOC that can be removed by surface aeration (fraction)

$$
1-\left(\mathrm{C}_{\mathrm{L}, \mathrm{e}} / \mathrm{C}_{\mathrm{L}, \mathrm{i}}\right)=1-\left[1+\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{VOC}} \cdot \theta\right]^{-1}
$$

If significant amount of the VOC is adsorbed or biodegraded, then results obtained with the above equation will be over estimated.

For completely mixed reactor with diffused aeration the equation is

$$
1-\left(\mathrm{C}_{\mathrm{L}, \mathrm{e}} / \mathrm{C}_{\mathrm{L}, \mathrm{i}}\right)=1-\left[1+\left(\mathrm{Q}_{\mathrm{g}} / \mathrm{Q}_{\mathrm{L}}\right)(\mathrm{Hc})\left(1-\mathrm{e}^{-\Phi}\right)\right]^{-1}
$$

Where, $\mathrm{Q}_{\mathrm{g}}=$ gas flow rate, $\mathrm{m}^{3} / \mathrm{sec}$;
$\mathrm{Q}_{\mathrm{L}}=$ Liquid flow rate, $\mathrm{m}^{3} / \mathrm{sec}$; and
$\Phi=$ saturation parameter $=\mathrm{K}_{\mathrm{L}} \mathrm{a}_{\mathrm{VOC}} \cdot \mathrm{V} /\left(\mathrm{Hc} . \mathrm{Q}_{\mathrm{g}}\right)$

Example: Determine amount of benzene that can be stripped in a completely mixed reactor equipped with diffused air aeration system. Assume following conditions:

1. Wastewaterflow rate $=1.0 \mathrm{MG} /$ day
2. Aeration tank volume $=0.25 \mathrm{MG}$
3. Depth of aeration $\operatorname{tank}=20 \mathrm{ft}$.
4. Air flow rate $=1750 \mathrm{ft}^{3} / \mathrm{min}$ at std. condition
5. Oxygen transfer rate $=6.2$ per hr
6. Influent concentration of benzene $=100 \mu \mathrm{~g} / \mathrm{ft}^{3}$
7. $\mathrm{Hc}=5.49 \times 10^{-3} \mathrm{~m}^{3}$. $\mathrm{atm} / \mathrm{mol}$
8. $\Psi=0.6$
9. Temperature $=20^{\circ} \mathrm{C}$

## Solution:

## Questions

1. Describe in short commonly used aeration devices used in aerobic wastewater treatment.
2. Explain in short the two-film theory of gas transfer in liquid, derive the expression for gas transfer rate in liquid and gas release from the liquid.
3. Explain in short how to evaluate $\mathrm{O}_{2}$ - transfer coefficient in water and wastewater.
4.
